The Strathprints institutional repository (<https://strathprints.strath.ac.uk>) is a digital archive of University of Strathclyde research outputs. It has been developed to disseminate open access research outputs, expose data about those outputs, and enable the management and persistent access to Strathclyde's intellectual output.

Multiplier analysis of re-spending rebound effects

Professor Karen Tuner, Antonios Katris
Centre for Energy Policy, University of Strathclyde

1.Introduction

Rebound effects occur when potential energy savings from an energy efficiency improvement are eroded as a result of a range of economic responses to changes in costs of energy services, incomes and prices throughout the economy. We focus on a particular type of rebound effect, which results from re-spending decisions as households realise savings due to reduced energy requirements.

2. Multipliers in our work

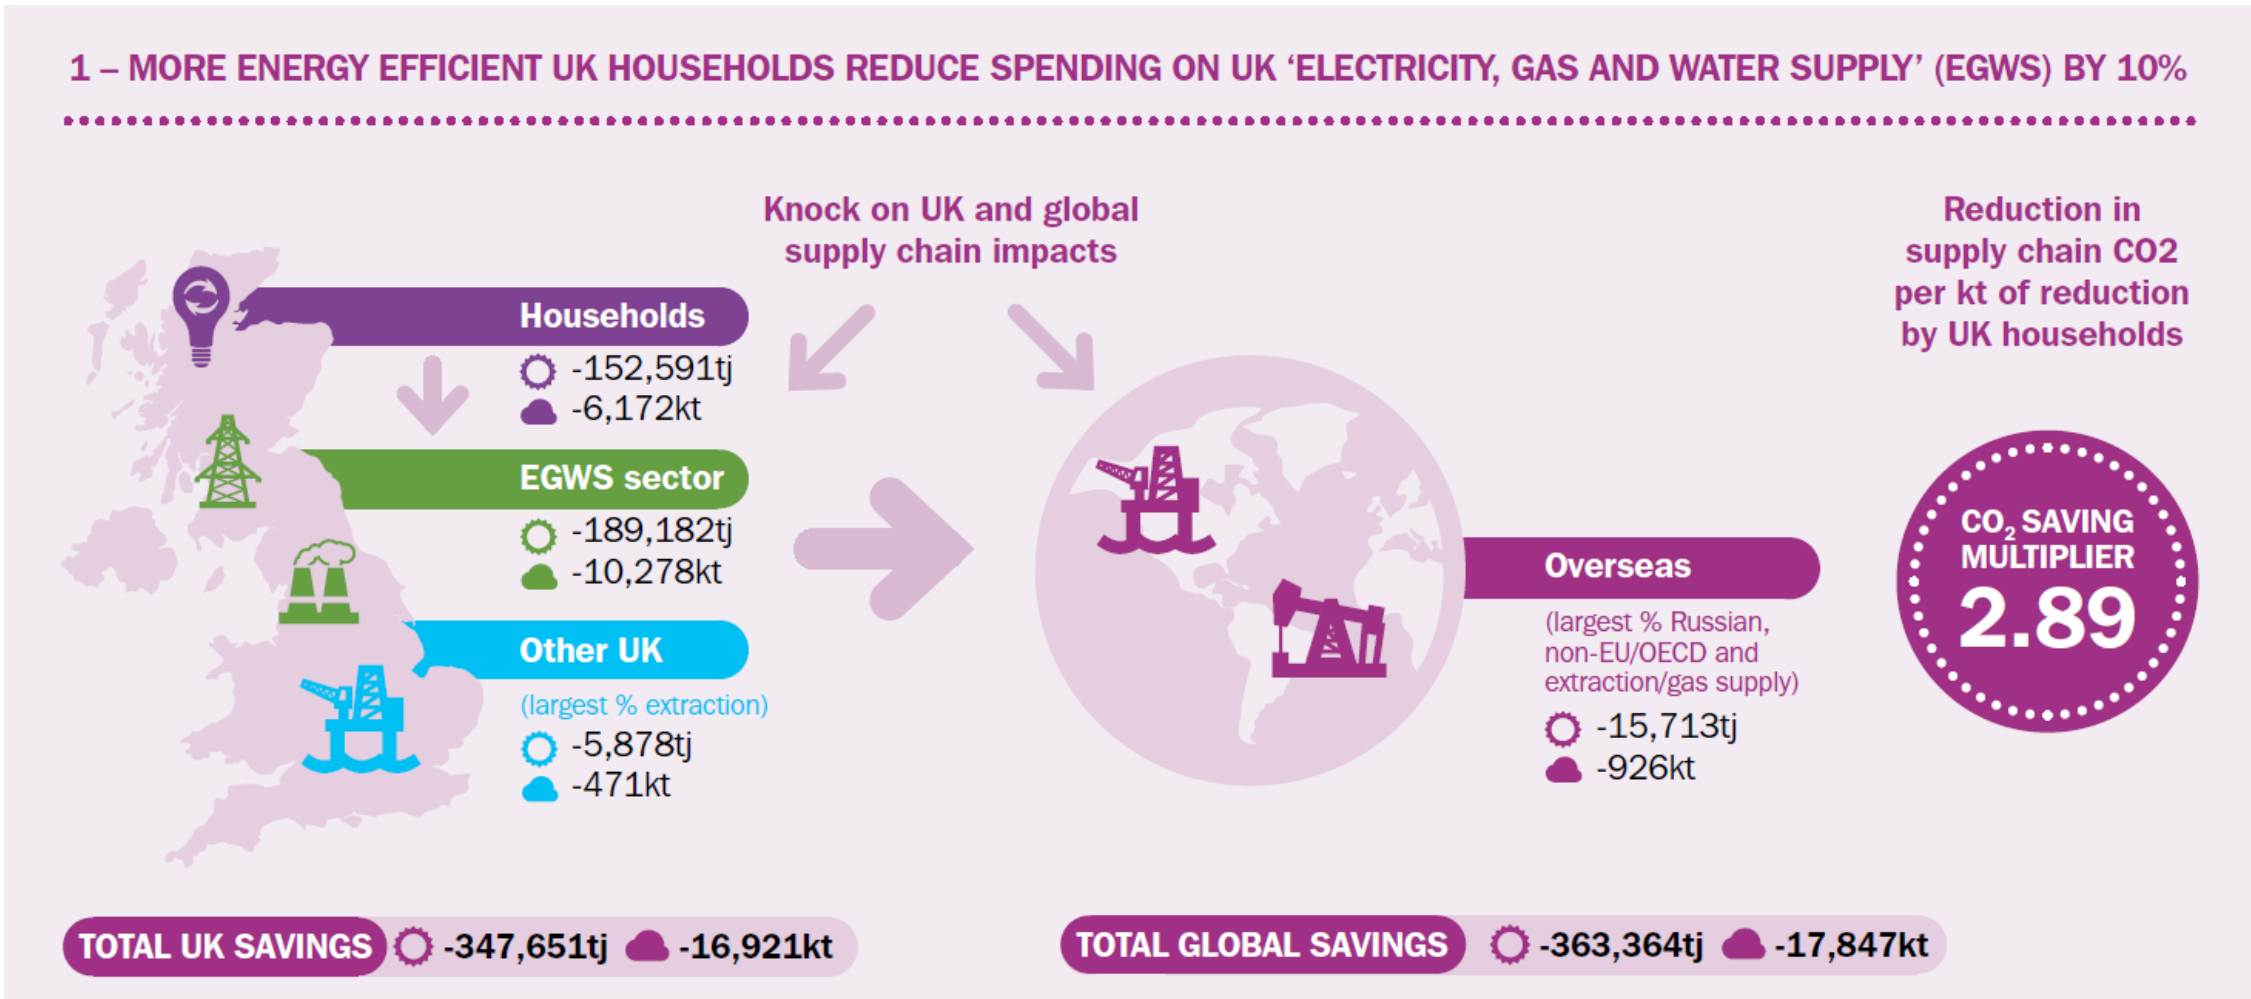

By using multiplier analysis we can estimate the impact that changes in final demand have in energy use/CO₂ emissions. The graph shows the increase to energy use and CO₂ emissions in a number of sectors, resulting by an increase of their final demand by £1m.

OUTPUT MULTIPLIERS (IMPACTS PER £1M SPEND)

3. A simple improved efficiency scenario

To explore how multipliers could be used to identify the impact throughout the economy as a result of improved energy efficiency, we use a simple illustrative scenario. We assume that improved energy efficiency in UK households leads to a 10% reduction in spending to UK EGWS.

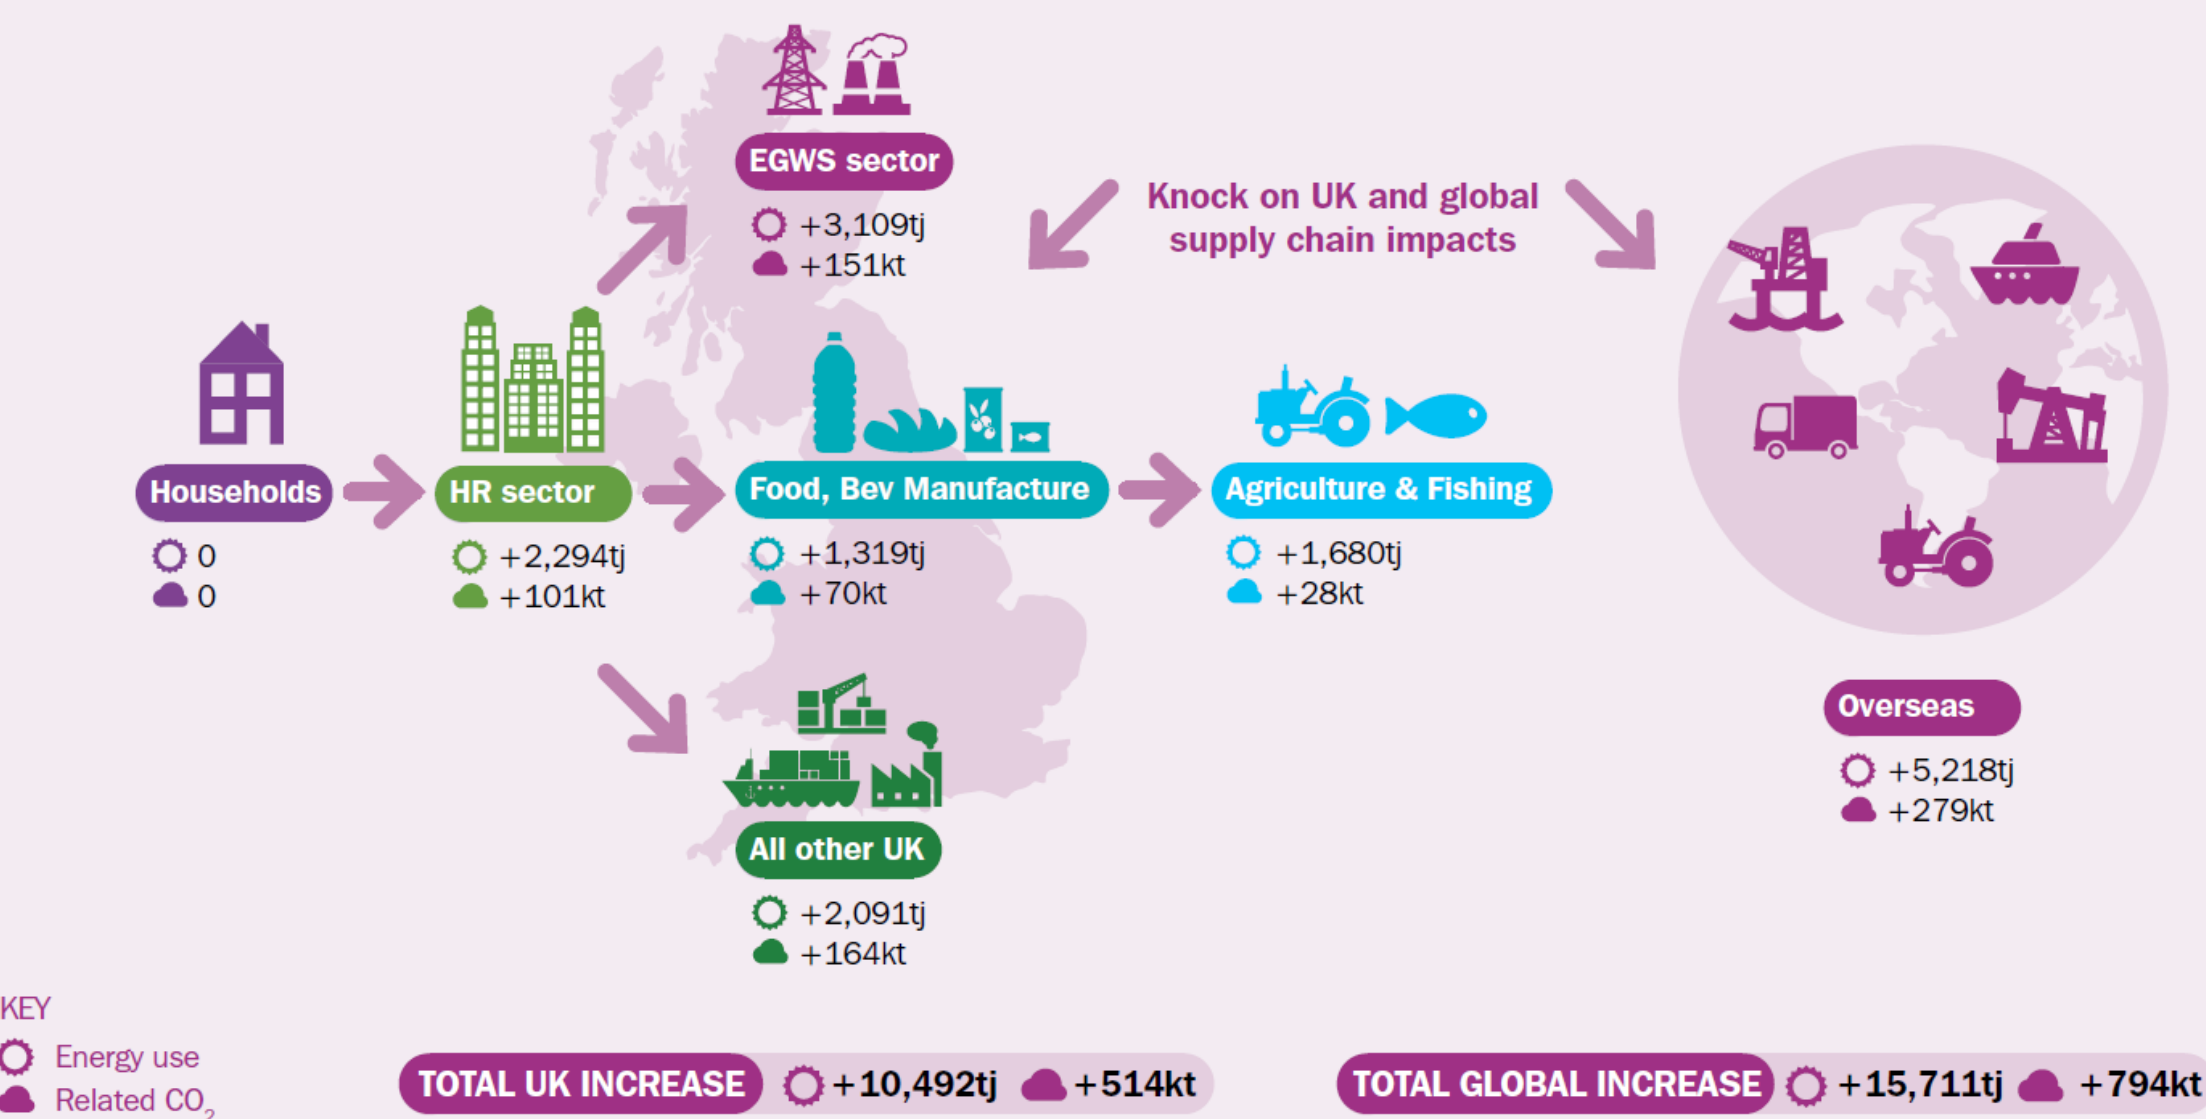

4. The Carbon Saving Multiplier

We propose the use of a carbon saving multiplier (CSM). CSM is calculated using the following formula.

$$CSM = \frac{\text{Change in embodied emissions}}{\text{Direct household emissions savings}}$$

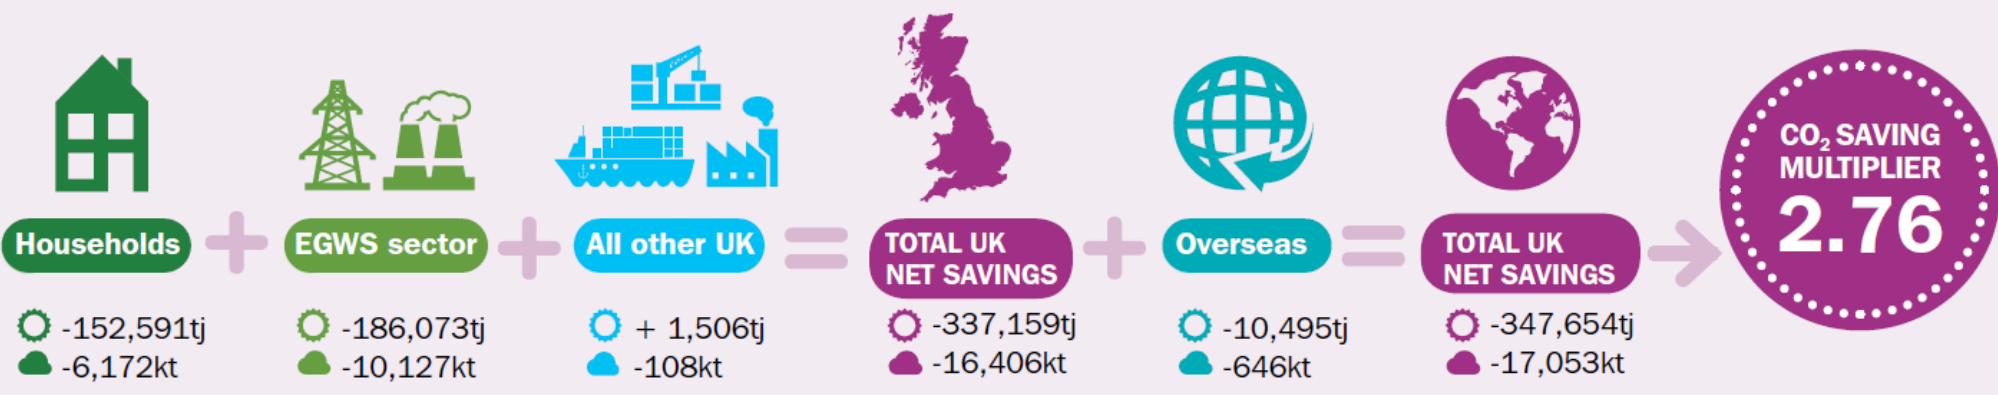

In the examined scenario this corresponds to the ratio of total global savings (-17,847 kt) over the direct savings of UK households (-6,172 kt) giving a CSM of 2.89. This is interpreted that for each kilo-tonne (kt) of CO₂ saved by UK households a further 1.89 kt are saved globally. However, when the savings from improved energy efficiency are re-spent then we a subsequent increase in energy use/CO₂ emissions of the sectors where the savings are re-spent, due to increased production to meet increased final demand.

2A – RE-SPEND SCENARIO 1: UK HOUSEHOLDS SWITCH SPENDING TO UK ‘HOTELS AND RESTAURANTS’ (HR)

As can be seen in Figure 2B, the increased energy use/CO₂ do not offset the savings achieved before any re-spending taking place. However, the CSM is eroded as a result of the decrease in total net savings.

2B – NET IMPACTS ON ENERGY USE AND RELATED CO₂ FROM EGWS TO HOTELS AND RESTAURANTS REALLOCATION

5. Erosion of the CSM

The CSM is eroded as a result of different re-spending decisions. The degree of erosion depends on the energy/CO₂ emissions intensity of the sector where re-spending is directed. The bar-chart shows the different levels of erosion under different re-spending scenarios compared to the original level of CSM.

CARBON SAVING MULTIPLIERS FROM REALLOCATION OF SPENDING FOR A ‘HEAT OR EAT’ EXAMPLE – REDUCTION IN SUPPLY CHAIN CO₂ PER KT REDUCTION BY HOUSEHOLDS

The policy briefing that this poster presents has been produced as an output of the project ‘Energy saving innovations and economy wide rebound effects’ which is funded by the EPSRC under the ‘Working with the End Use Energy Demand Centres’ call. The project is led by Professor Karen Turner, Director of the Centre for Energy Policy at the University of Strathclyde. Hard copies of the policy briefing can be found at the stand of the University of Strathclyde
